switc to Brush mode. Choose a new color (sa yellow) and large closed glyph, and transiently paint the case with a very low value on palmitic (Figure 7). This case also has a very high value for oleic acid, and low value for linolenic acid.

Figure 7: Brushing in a parallel coordinates display reveals and outlier in palmitic, oleic and linolenic acids.

Using the Case clusters panel from the Brush controlsk the sho c box to the Region 1 cases back into the plot. Now using the File menu output the data, sa the colors and glyphs that have been created during this session.

This has been a brief introduction to the use of ggobi. The following section contains more detailed information on the functionality.

The only essential le is the one containing the data itself. Each line in the le contains one row of the input data matrix, and lines must be separated by carriage returns. Columns, or variables, can be separated by any number of tabs or spaces. The le needs to have the su x *.dat*.

You can supply variable and case labels in associated les. Variable (column) labels can be in a le named

The Update button at the bottom of the window will reset the contents of the table in case it isn't responding to changes in the displays. The Rescale button will cause the views to be redrawn as if any hidden points are no longer in the data: that is, the points that are shown will be scaled to fill the viewing area of the plot.

If you want all plots to rescale immediately when you assign new values, turn on *Rescale* toggle. Finally, click on the

11 Di erences from xgobi

In this section, we summarize the key di erences between ggobi and xgobi for those readers who are already familiar with xgobi.

11.1 Multiple displays

The rst thing you'll notice when you look at a ggobi display is that the plotting window has become separated from the control panels. The main reason for that change is so that a ggobi
